Flood Insurance Rate Map (FIRM)

## FLOOD INSURANCE STUDY REPORT CITY AND BOROUGH OF JUNEAU, ALASKA

## **SECTION 1.0 – INTRODUCTION**

## 1.1 The National Flood Insurance Program

The National Flood Insurance Program (NFIP) is a voluntary Federal program that enables property owners in participating communities to purchase insurance protection against losses from flooding. This insurance is designed to provide an alternative to disaster assistance to meet the escalating costs of repairing damage to buildings and their contents caused by floods.

For decades, the national response to flood disasters was generally limited to constructing flood-control works such as dams, levees, sea-walls, and the like, and providing disaster relief to flood victims. This approach did not reduce losses nor did it discourage unwise development. In some instances, it may have actually encouraged additional development. To compound the problem, the public generally could not buy flood coverage from insurance companies, and building techniques to reduce flood damage were often overlooked.

In the face of mounting flood losses and escalating costs of disaster relief to the general taxpayers, the U.S. Congress created the NFIP. The intent was to reduce future flood damage through community floodplain management ordinances, and provide protection for property owners against potential losses through an insurance mechanism that requires a premium to be paid for the protection.

The U.S. Congress established the NFIP on August 1, 1968, with the passage of the National Flood Insurance Act of 1968. The NFIP was broadened and modified with the passage of the Flood Disaster Protection Act of 1973 and other legislative measures. It was further modified by the National Flood Insurance Reform Act of 1994 and the Flood Insurance Reform Act of 2004. The NFIP is administered by the Federal Emergency Management Agency (FEMA), which is a component of the Department of Homeland Security (DHS).

Participation in the NFIP is based on an agreement between local communities and the Federal Government. If a community adopts and enforces floodplain management regulations to reduce future flood risks to new construction and substantially improved structures in Special Flood Hazard Areas (SFHAs), the Federal Government will make flood insurance available within the community as a financial protection against flood losses. The community's floodplain management regulations must meet or exceed criteria established in accordance with Title 44 Code of Federal Regulations (CFR) Part 60, *Criteria for land Management and Use*.

SFHAs are delineated on the community's Flood Insurance Rate Maps (FIRMs). Under the NFIP, buildings that were built before the flood hazard was identified on the community's FIRMs are generally referred to as "Pre-FIRM" buildings. When the NFIP was created, the U.S. Congress recognized that insurance for Pre-FIRM buildings would be prohibitively expensive if the premiums were not subsidized by the Federal Government. Congress also recognized that most of these floodprone buildings were built by individuals who did not have sufficient knowledge of the flood hazard to make informed decisions. The NFIP requires that full actuarial rates reflecting the complete flood risk be charged on all buildings constructed or substantially improved on or after the effective date of the initial FIRM for the community or after December 31, 1974, whichever is later. These buildings are generally referred to as "Post-FIRM" buildings.

## **1.2** Purpose of this Flood Insurance Study Report

This Flood Insurance Study (FIS) report revises and updates information on the existence and severity of flood hazards for the study area. The studies described in this report developed flood hazard data that will be used to establish actuarial flood insurance rates and to assist communities in efforts to implement sound floodplain management.

In some states or communities, floodplain management criteria or regulations may exist that are more restrictive than the minimum Federal requirements. Contact your State NFIP Coordinator to ensure that any higher State standards are included in the community's regulations.

## **1.3** Jurisdictions Included in the Flood Insurance Study Project

This FIS Report covers the entire geographic area of the City and Borough of Juneau, Alaska.

The jurisdictions that are included in this project area, along with the Community Identification Number (CID) for each community and the 8-digit Hydrologic Unit Codes (HUC-8) sub-basins affecting each, are shown in Table 1. The FIRM panel numbers that affect each community are listed. If the flood hazard data for the community is not included in this FIS Report, the location of that data is identified.

The location of flood hazard data for participating communities in multiple jurisdictions is also indicated in the table.

Jurisdictions that have no identified SFHAs as of the effective date of this study are indicated in the table. Changed conditions in these communities (such as urbanization or annexation) or the availability of new scientific or technical data about flood hazards could make it necessary to determine SFHAs in these jurisdictions in the future.

\*PANEL NOT PRINTED – NO SPECIAL FLOOD HAZARD AREAS

## 1.4 Considerations for using this Flood Insurance Study Report

The NFIP encourages State and local governments to implement sound floodplain management programs. To assist in this endeavor, each FIS Report provides floodplain data, which may include a combination of the following: 10-, 4-, 2-, 1-, and 0.2-percent annual chance flood elevations (the 1% annual chance flood elevation is also referred to as the Base Flood Elevation (BFE)); delineations of the 1% annual chance and 0.2% annual chance floodplains; and 1% annual chance floodway. This information is presented on the FIRM and/or in many components of the FIS Report, including Flood Profiles, Floodway Data tables, Summary of Non-Coastal Stillwater Elevations tables, and Coastal Transect Parameters tables (not all components may be provided for a specific FIS).

This section presents important considerations for using the information contained in this FIS Report and the FIRM, including changes in format and content. Figures 1, 2, and 3 present information that applies to using the FIRM with the FIS Report.

• Part or all of this FIS Report may be revised and republished at any time. In addition, part of this FIS Report may be revised by a Letter of Map Revision (LOMR), which does not involve republication or redistribution of the FIS Report. Refer to Section 6.5 of this FIS Report for information about the process to revise the FIS Report and/or FIRM.

It is, therefore, the responsibility of the user to consult with community officials by contacting the community repository to obtain the most current FIS Report components. Communities participating in the NFIP have established repositories of flood hazard data for floodplain management and flood insurance purposes. Community map repository addresses are provided in Table 30, "Map Repositories," within this FIS Report.

 New FIS Reports are frequently developed for multiple communities, such as entire counties. A countywide FIS Report incorporates previous FIS Reports for individual communities and the unincorporated area of the county (if not jurisdictional) into a single document and supersedes those documents for the purposes of the NFIP.

The initial Countywide FIS Report for the City and Borough of Juneau, Alaska became effective on May 9, 1970. Refer to Table 27 for information about subsequent revisions to the FIRMs.

• FEMA does not impose floodplain management requirements or special insurance

ratings based on Limit of Moderate Wave Action (LiMWA) delineations at this time. The LiMWA represents the approximate landward limit of the 1.5-foot breaking wave. If the LiMWA is shown on the FIRM, it is being provided by FEMA as information only. For communities that do adopt Zone VE building standards in the area defined by the LiMWA, additional Community Rating System (CRS) credits are available. Refer to Section 2.5.4 for additional information about the LiMWA.

The CRS is a voluntary incentive program that recognizes and encourages community floodplain management activities that exceed the minimum NFIP requirements. Visit the FEMA Web site at http://www.fema.gov or contact your appropriate FEMA Regional Office for more information about this program.

 Previous FIS Reports and FIRMs may have included levees that were accredited as reducing the risk associated with the 1% annual chance flood based on the information available and the mapping standards of the NFIP at that time. For FEMA to continue to accredit the identified levees, the levees must meet the criteria of the Code of Federal Regulations, Title 44, Section 65.10 (44 CFR 65.10), titled "Mapping of Areas Protected by Levee Systems."

Since the status of levees is subject to change at any time, the user should contact the appropriate agency for the latest information regarding levees presented in this FIS Report. For levees owned or operated by the U.S. Army Corps of Engineers (USACE), information may be obtained from the USACE National Levee Database (<u>nld.usace.army.mil</u>). For all other levees, the user is encouraged to contact the appropriate local community.

• FEMA has developed a *Guide to Flood Maps* (FEMA 258) and online tutorials to assist users in accessing the information contained on the FIRM. These include how to read panels and step-by-step instructions to obtain specific information. To obtain this guide and other assistance in using the FIRM, visit the FEMA Web site at www.fema.gov/online-tutorials.

The FIRM Index in Figure 1 shows the overall FIRM panel layout within City and Borough of Juneau, and also displays the panel number and effective date for each FIRM panel in the county. Other information shown on the FIRM Index includes community boundaries, flooding sources, watershed boundaries, and United States Geological Survey (USGS) Hydrologic Unit Code – 8 (HUC-8) codes.

MAP REVISED SEPTEMBER 18, 2020 Each FIRM panel may contain specific notes to the user that provide additional information regarding the flood hazard data shown on that map. However, the FIRM panel does not contain enough space to show all the notes that may be relevant in helping to better understand the information on the panel. Figure 2 contains the full list of these notes.

## Figure 2: FIRM Notes to Users

## NOTES TO USERS

For information and questions about this map, available products associated with this FIRM including historic versions of this FIRM, how to order products, or the National Flood Insurance Program in general, please call the FEMA Map Information eXchange at 1-877-FEMA-MAP (1-877-336-2627) or visit the FEMA Map Service Center website at http://msc.fema.gov. Available products may include previously issued Letters of Map Change, a Flood Insurance Study Report, and/or digital versions of this map. Many of these products can be ordered or obtained directly from the website. Users may determine the current map date for each FIRM panel by visiting the FEMA Map Service Center website or by calling the FEMA Map Information eXchange.

Communities annexing land on adjacent FIRM panels must obtain a current copy of the adjacent panel as well as the current FIRM Index. These may be ordered directly from the Map Service Center at the number listed above.

For community and countywide map dates, refer to Table 28 in this FIS Report.

To determine if flood insurance is available in the community, contact your insurance agent or call the National Flood Insurance Program at 1-800-638-6620.

<u>PRELIMINARY FIS REPORT</u>: FEMA maintains information about map features, such as street locations and names, in or near designated flood hazard areas. Requests to revise information in or near designated flood hazard areas may be provided to FEMA during the community review period, at the final Consultation Coordination Officer's meeting, or during the statutory 90-day appeal period. Approved requests for changes will be shown on the final printed FIRM.

The map is for use in administering the NFIP. It may not identify all areas subject to flooding, particularly from local drainage sources of small size. Consult the community map repository to find updated or additional flood hazard information.

BASE FLOOD ELEVATIONS: For more detailed information in areas where Base Flood Elevations (BFEs) and/or floodways have been determined, consult the Flood Profiles and Floodway Data and/or Summary of Stillwater Elevations tables within this FIS Report. Use the flood elevation data within the FIS Report in conjunction with the FIRM for construction and/or floodplain management.

<u>FLOODWAY INFORMATION</u>: Boundaries of the floodways were computed at cross sections and interpolated between cross sections. The floodways were based on hydraulic considerations with regard to requirements of the National Flood Insurance Program. Floodway widths and other pertinent floodway data are provided in the FIS Report for this jurisdiction.

## Figure 2. FIRM Notes to Users

<u>FLOOD CONTROL STRUCTURE INFORMATION</u>: Certain areas not in Special Flood Hazard Areas may be protected by flood control structures. Refer to Section 4.3 "Non-Levee Flood Protection Measures" of this FIS Report for information on flood control structures for this jurisdiction.

<u>PROJECTION INFORMATION</u>: The projection used in the preparation of the map was NAD 1983 StatePlane Alaska 1 FIPS 5001 Feet. The horizontal datum was NAD83, GRS1980 spheroid. Differences in datum, spheroid, projection or State Plane zones used in the production of FIRMs for adjacent jurisdictions may result in slight positional differences in map features across jurisdiction boundaries. These differences do not affect the accuracy of the FIRM.

<u>ELEVATION DATUM</u>: Flood elevations on the FIRM are referenced to the Mean Lower Low Water (MLLW). The borough-wide conversion factor from NGDVD29 to MLLW is minus 8.2 feet (Reference 9). These flood elevations must be compared to structure and ground elevations referenced to the same vertical datum. For information regarding conversion between the National Geodetic Vertical Datum of 1929 and the MLWW, visit the National Geodetic Survey website at http://www.ngs.noaa.gov/ or contact the National Geodetic Survey at the following address:

NGS Information Services NOAA, N/NGS12 National Geodetic Survey SSMC-3, #9202 1315 East-West Highway Silver Spring, Maryland 20910-3282 (301) 713-3242

Local vertical monuments may have been used to create the map. To obtain current monument information, please contact the appropriate local community listed in Table 31 of this FIS Report.

BASE MAP INFORMATION: Base map information shown on the FIRM was provided by in digital format by the City and Borough of Juneau, Alaska Deptarment of Natural Resources (AK DNR), Bureau of Land Management (BLM), U.S. Forest Service (USFS), and the United States Geological Survey (USGS). This information was compiled at varius map scales during the time period 1997 – 2016. Other information was derived from digital orthophotography at a 6-inch resolution from photography dated 2013. For information about base maps, refer to Section 6.2 "Base Map" in this FIS Report.

Corporate limits shown on the map are based on the best data available at the time of publication. Because changes due to annexations or de-annexations may have occurred after the map was published, map users should contact appropriate community officials to verify current corporate limit locations.

## Figure 2. FIRM Notes to Users

## NOTES FOR FIRM INDEX

<u>REVISIONS TO INDEX</u>: As new studies are performed and FIRM panels are updated within City and Borough of Juneau, Alaska, corresponding revisions to the FIRM Index will be incorporated within the FIS Report to reflect the effective dates of those panels. Please refer to Table 28 of this FIS Report to determine the most recent FIRM revision date for each community. The most recent FIRM panel effective date will correspond to the most recent index date.

## SPECIAL NOTES FOR SPECIFIC FIRM PANELS

This Notes to Users section was created specifically for City and Borough of Juneau, Alaska, effective "September 18, 2020".

<u>FLOOD RISK REPORT</u>: A Flood Risk Report (FRR) may be available for many of the flooding sources and communities referenced in this FIS Report. The FRR is provided to increase public awareness of flood risk by helping communities identify the areas within their jurisdictions that have the greatest risks. Although non-regulatory, the information provided within the FRR can assist communities in assessing and evaluating mitigation opportunities to reduce these risks. It can also be used by communities developing or updating flood risk mitigation plans. These plans allow communities to identify and evaluate opportunities to reduce potential loss of life and property. However, the FRR is not intended to be the final authoritative source of all flood risk data for a project area; rather, it should be used with other data sources to paint a comprehensive picture of flood risk.

<b>SPECIAL FLOOD HAZARD AREAS:</b> The 1% annual chance flood, also known as the base flood or 100-year flood, has a 1% chance of happening or being exceeded each year. Special Flood Hazard Areas are subject to flooding by the 1% annual chance flood. The Base Flood Elevation is the water surface elevation of the 1% annual chance flood. The floodway is the channel of a stream plus any adjacent floodplain areas that must be kept free of encroachment so that the 1% annual chance flood can be carried without substantial increases in flood heights. See note for specific types. If the floodway is too narrow to be shown, a note is shown.				
	Special Flood Hazard Areas subject to inundation by the 1% annual chance flood (Zones A, AE, AH, AO, AR, A99, V and VE)			
Zone A	The flood insurance rate zone that corresponds to the 1% annual chance floodplains. No base (1% annual chance) flood elevations (BFEs) or depths are shown within this zone.			
Zone AE	The flood insurance rate zone that corresponds to the 1% annual chance floodplains. Base flood elevations derived from the hydraulic analyses are shown within this zone, either at cross section locations or as static whole-foot elevations that apply throughout the zone.			
Zone AH	The flood insurance rate zone that corresponds to the areas of 1% annual chance shallow flooding (usually areas of ponding) where average depths are between 1 and 3 feet. Whole-foot BFEs derived from the hydraulic analyses are shown at selected intervals within this zone.			
Zone AO	The flood insurance rate zone that corresponds to the areas of 1% annual chance shallow flooding (usually sheet flow on sloping terrain) where average depths are between 1 and 3 feet. Average whole-foot depths derived from the hydraulic analyses are shown within this zone.			
Zone AR	The flood insurance rate zone that corresponds to areas that were formerly protected from the 1% annual chance flood by a flood control system that was subsequently decertified. Zone AR indicates that the former flood control system is being restored to provide protection from the 1% annual chance or greater flood.			
Zone A99	The flood insurance rate zone that corresponds to areas of the 1% annual chance floodplain that will be protected by a Federal flood protection system where construction has reached specified statutory milestones. No base flood elevations or flood depths are shown within this zone.			
Zone V	The flood insurance rate zone that corresponds to the 1% annual chance coastal floodplains that have additional hazards associated with storm waves. Base flood elevations are not shown within this zone.			
Zone VE	Zone VE is the flood insurance rate zone that corresponds to the 1% annual chance coastal floodplains that have additional hazards associated with storm waves. Base flood elevations derived from the coastal analyses are shown within this zone as static whole-foot elevations that apply throughout the zone.			
	Regulatory Floodway determined in Zone AE.			

	Non-encroachment zone (see Section 2.4 of this FIS Report for more information)
FLOOD INSURANCE IS NOT AVAILABLE FOR STRUCTURES NEWLY BUILT OR SUBSTANTIALLY IMPROVED ON OR AFTER APRIL 8, 1987, IN THE DESIGNATED COLORADO RIVER FLOODWAY	The Colorado River Floodway was established by Congress in the Colorado River Floodway Protection Act of 1986, Public Law 99-450 (100 Statute 1129). The Act imposes certain restrictions within the Floodway.
OTHER AREAS OF FLOO	D HAZARD
	Shaded Zone X: Areas of 0.2% annual chance flood hazards and areas of 1% annual chance flood hazards with average depths of less than 1 foot or with drainage areas less than 1 square mile.
	Future Conditions 1% Annual Chance Flood Hazard – Zone X: The flood insurance rate zone that corresponds to the 1% annual chance floodplains that are determined based on future-conditions hydrology. No base flood elevations or flood depths are shown within this zone.
	Area with Reduced Flood Risk due to Levee: Areas where an accredited levee, dike, or other flood control structure has reduced the flood risk from the 1% annual chance flood. See Notes to Users for important information.
OTHER AREAS	
	Zone D (Areas of Undetermined Flood Hazard): The flood insurance rate zone that corresponds to unstudied areas where flood hazards are undetermined, but possible.
NO SCREEN	Unshaded Zone X: Areas of minimal flood hazard.
FLOOD HAZARD AND OT	HER BOUNDARY LINES
(ortho) (vector)	Flood Zone Boundary (white line on ortho-photography-based mapping; gray line on vector-based mapping)
	Limit of Study
	Jurisdiction Boundary
	Limit of Moderate Wave Action (LiMWA): Indicates the inland limit of the area affected by waves greater than 1.5 feet

## SECTION 2.0 – FLOODPLAIN MANAGEMENT APPLICATIONS

## 2.1 Floodplain Boundaries

To provide a national standard without regional discrimination, the 1% annual chance (100-year) flood has been adopted by FEMA as the base flood for floodplain management purposes. The 0.2% annual chance (500-year) flood is employed to indicate additional areas of flood hazard in the community.

Each flooding source included in the project scope has been studied and mapped using professional engineering and mapping methodologies that were agreed upon by FEMA and the City and Borough of Juneau, Alaska as appropriate to the risk level. Flood risk is evaluated based on factors such as known flood hazards and projected impact on the built environment. Engineering analyses were performed for each studied flooding source to calculate its 1% annual chance flood elevations; elevations corresponding to other floods (e.g. 10-, 4-, 2-, 0.2-percent annual chance, etc.) may have also been computed for certain flooding sources. Engineering models and methods are described in detail in Section 5.0 of this FIS Report. The modeled elevations at cross sections were used to delineate the floodplain boundaries on the FIRM; between cross sections, the boundaries were interpolated using elevation data from various sources. More information on specific mapping methods is provided in Section 6.0 of this FIS Report.

Depending on the accuracy of available topographic data (Table 23), study methodologies employed (Section 5.0), and flood risk, certain flooding sources may be mapped to show both the 1% and 0.2% annual chance floodplain boundaries, regulatory water surface elevations (BFEs), and/or a regulatory floodway. Similarly, other flooding sources may be mapped to show only the 1% annual chance floodplain boundary on the FIRM, without published water surface elevations. In cases where the 1% and 0.2% annual chance floodplain boundary is shown on the FIRM. Figure 3, "Map Legend for FIRM", describes the flood zones that are used on the FIRMs to account for the varying levels of flood risk that exist along flooding sources within the project area. Table 2 and Table 3 indicate the flood zone designations for each flooding source and each community within the City and Borough of Juneau, Alaska respectively.

Table 2, "Flooding Sources Included in this FIS Report," lists each flooding source, including its study limits, affected communities, mapped zone on the FIRM, and the completion date of its engineering analysis from which the flood elevations on the FIRM and in the FIS Report were derived. Descriptions and dates for the latest hydrologic and hydraulic analyses of the flooding sources are shown in Table 13. Floodplain boundaries for these flooding sources are shown on the FIRM (published separately) using the symbology described in Figure 3. On the map, the 1% annual chance floodplain corresponds to the SFHAs. The 0.2% annual chance floodplain shows areas that, although out of the regulatory floodplain, are still subject to flood hazards.

Small areas within the floodplain boundaries may lie above the flood elevations but cannot be shown due to limitations of the map scale and/or lack of detailed topographic data. The procedures to remove these areas from the SFHA are described in Section 6.5 of this FIS Report.

Flooding Source	Community	Downstream Limit	Upstream Limit	HUC-8 Sub- Basin(s)	Length (mi) (streams or coastlines)	Area (mi <sup>2</sup> ) (estuaries or ponding)	Floodway (Y/N)	Zone shown on FIRM	Date of Analysis

## Table 2: Flooding Sources Included in this FIS Report (continued)

## 2.2 Floodways

Encroachment on floodplains, such as structures and fill, reduces flood-carrying capacity, increases flood heights and velocities, and increases flood hazards in areas beyond the encroachment itself. One aspect of floodplain management involves balancing the economic gain from floodplain development against the resulting increase in flood hazard.

For purposes of the NFIP, a floodway is used as a tool to assist local communities in balancing floodplain development against increasing flood hazard. With this approach, the area of the 1% annual chance floodplain on a river is divided into a floodway and a floodway fringe based on hydraulic modeling. The floodway is the channel of a stream, plus any adjacent floodplain areas, that must be kept free of encroachment in order to carry the 1% annual chance flood. The floodway fringe is the area between the floodway and the 1% annual chance floodplain boundaries where encroachment is permitted. The floodway must be wide enough so that the floodway fringe could be completely obstructed without increasing the water surface elevation of the 1% annual chance flood more than 1 foot at any point. Typical relationships between the floodway and the floodway fringe and their significance to floodplain development are shown in Figure 4.

To participate in the NFIP, Federal regulations require communities to limit increases caused by encroachment to 1.0 foot, provided that hazardous velocities are not produced. Regulations for Alaska require communities in the City and Borough of Juneau to limit increases caused by encroachment to 0.5 foot and several communities have adopted additional restrictions. The floodways in this project are presented to local agencies as minimum standards that can be adopted directly or that can be used as a basis for additional floodway projects.

#### **Figure 4: Floodway Schematic**

Floodway widths presented in this FIS Report and on the FIRM were computed at cross sections. Between cross sections, the floodway boundaries were interpolated. For certain stream segments, floodways were adjusted so that the amount of floodwaters conveyed on each side of the floodplain would be reduced equally. The results of the floodway computations have been tabulated for selected cross sections and are shown in Table 24, "Floodway Data."

All floodways that were developed for this Flood Risk Project are shown on the FIRM using the symbology described in Figure 3. In cases where the floodway and I% annual chance floodplain boundaries are either close together or collinear, only the floodway boundary has been shown on the FIRM. For information about the delineation of floodways on the FIRM, refer to Section 6.3.

#### 2.3 Base Flood Elevations

The hydraulic characteristics of flooding sources were analyzed to provide estimates of the elevations of floods of the selected recurrence intervals. The Base Flood Elevation (BFE) is the elevation of the 1% annual chance flood. These BFEs are most commonly rounded to the whole foot, as shown on the FIRM, but in certain circumstances or locations they may be rounded to 0.1 foot. Cross section lines shown on the FIRM may also be labeled with the BFE rounded to 0.1 foot. Whole-foot BFEs derived from engineering analyses that apply to coastal areas, areas of ponding, or other static areas with little elevation change may also be shown at selected intervals on the FIRM.

Cross sections with BFEs shown on the FIRM correspond to the cross sections shown in the Floodway Data table and Flood Profiles in this FIS Report. BFEs are primarily intended

for flood insurance rating purposes. For construction and/or floodplain management purposes, users are cautioned to use the flood elevation data presented in this FIS Report in conjunction with the data shown on the FIRM.

## 2.4 Non-Encroachment Zones

Some States and communities use non-encroachment zones to manage floodplain development. While not a FEMA designated floodway, the non-encroachment zone represents that area around the stream that should be reserved to convey the 1% annual chance flood event.

Regulations for Alaska require communities in the City and Borough of Juneau to limit increases caused by encroachment to 1.0 foot.

Non-encroachment determinations may be delineated where it is not possible to delineate floodways because specific channel profiles with bridge and culvert geometry were not developed. Any non-encroachment determinations for this Flood Risk Project have been tabulated for selected cross sections and are shown in Table 25, "Flood Hazard and Non-Encroachment Data for Selected Streams."

## 2.5 Coastal Flood Hazard Areas

For most areas along rivers, streams, and small lakes, BFEs and floodplain boundaries are based on the amount of water expected to enter the area during a 1% annual chance flood and the geometry of the floodplain. Floods in these areas are typically caused by storm events. However, for areas on or near ocean coasts, large rivers, or large bodies of water, BFE and floodplain boundaries may need to be based on additional components, including storm surges and waves. Communities on or near ocean coasts face flood hazards caused by offshore seismic events as well as storm events.

Coastal flooding sources that are included in this Flood Risk Project are shown in Table 2.

### 2.5.1 Water Elevations and the Effects of Waves

Specific terminology is used in coastal analyses to indicate which components have been included in evaluating flood hazards.

The stillwater elevation (SWEL or still water level) is the surface of the water resulting from astronomical tides, storm surge, and freshwater inputs, but excluding wave setup contribution or the effects of waves.

- Astronomical tides are periodic rises and falls in large bodies of water caused by the rotation of the earth and by the gravitational forces exerted by the earth, moon and sun.
- Storm surge is the additional water depth that occurs during large storm events. These events can bring air pressure changes and strong winds that force water up against the shore.
- *Freshwater inputs* include rainfall that falls directly on the body of water, runoff from surfaces and overland flow, and inputs from rivers.

The 1% annual chance stillwater elevation is the stillwater elevation that has been calculated for a storm surge from a 1% annual chance storm. The 1% annual chance storm surge can be determined from analyses of tidal gage records, statistical study of regional historical storms, or other modeling approaches. Stillwater elevations for storms of other frequencies can be developed using similar approaches.

The total stillwater elevation (also referred to as the mean water level) is the stillwater elevation plus wave setup contribution but excluding the effects of waves.

• *Wave setup* is the increase in stillwater elevation at the shoreline caused by the reduction of waves in shallow water. It occurs as breaking wave momentum is transferred to the water column.

Like the stillwater elevation, the total stillwater elevation is based on a storm of a particular frequency, such as the 1% annual chance storm. Wave setup is typically estimated using standard engineering practices or calculated using models, since tidal gages are often sited in areas sheltered from wave action and do not capture this information.

Coastal analyses may examine the effects of overland waves by analyzing storm-induced erosion, overland wave propagation, wave runup, and/or wave overtopping.

- *Storm-induced erosion* is the modification of existing topography by erosion caused by a specific storm event, as opposed to general erosion that occurs at a more constant rate.
- Overland wave propagation describes the combined effects of variation in ground elevation, vegetation, and physical features on wave characteristics as waves move onshore.
- *Wave runup* is the uprush of water from wave action on a shore barrier. It is a function of the roughness and geometry of the shoreline at the point where the stillwater elevation intersects the land.
- *Wave overtopping* refers to wave runup that occurs when waves pass over the crest of a barrier.

## Figure 5: Wave Runup Transect Schematic

### 2.5.2 Floodplain Boundaries and BFEs for Coastal Areas

For coastal communities along the Atlantic and Pacific Oceans, the Gulf of Mexico, the Great Lakes, and the Caribbean Sea, flood hazards must take into account how storm surges, waves, and extreme tides interact with factors such as topography and vegetation. Storm surge and waves must also be considered in assessing flood risk for certain communities on rivers or large inland bodies of water.

Beyond areas that are affected by waves and tides, coastal communities can also have riverine floodplains with designated floodways, as described in previous sections.

#### **Floodplain Boundaries**

In many coastal areas, storm surge is the principle component of flooding. The extent of the 1% annual chance floodplain in these areas is derived from the total stillwater elevation (stillwater elevation including storm surge plus wave setup) for the 1% annual chance storm. The methods that were used for calculation of total stillwater elevations for coastal areas are described in Section 5.3 of this FIS Report. Location of total stillwater elevations for coastal areas are shown in Figure 8, "1% Annual Chance Total Stillwater Levels for Coastal Areas."

In some areas, the 1% annual chance floodplain is determined based on the limit of wave runup or wave overtopping for the 1% annual chance storm surge. The methods that were used for calculation of wave hazards are described in Section 5.3 of this FIS Report.

Table 26 presents the types of coastal analyses that were used in mapping the 1% annual chance floodplain in coastal areas.

#### **Coastal BFEs**

Coastal BFEs are calculated as the total stillwater elevation (stillwater elevation including storm surge plus wave setup) for the 1% annual chance storm plus the additional flood hazard from overland wave effects (storm-induced erosion, overland wave propagation, wave runup and wave overtopping).

Where they apply, coastal BFEs are calculated along transects extending from offshore to the limit of coastal flooding onshore. Results of these analyses are accurate until local topography, vegetation, or development type and density within the community undergoes major changes.

Parameters that were included in calculating coastal BFEs for each transect included in this FIS Report are presented in Table 17 "Coastal Transect Parameters." The locations of transects are shown in Figure 9, "Transect Location Map." More detailed information about the methods used in coastal analyses and the results of intermediate steps in the coastal analyses are presented in Section 5.3 of this FIS Report. Additional information on specific mapping methods is provided in Section 6.4 of this FIS Report.

## 2.5.3 Coastal High Hazard Areas

This section is not applicable to this Flood Risk Project.

Figure 6, "Coastal Transect Schematic," illustrates the relationship between the base flood elevation, the 1% annual chance stillwater elevation, and the ground profile as well as the location of the Zone VE and Zone AE areas in an area without a PFD subject to overland wave propagation. This figure also illustrates energy dissipation and regeneration of a wave as it moves inland.

Methods used in coastal analyses in this Flood Risk Project are presented in Section 5.3 and mapping methods are provided in Section 6.4 of this FIS Report.

Coastal floodplains are shown on the FIRM using the symbology described in Figure 3, "Map Legend for FIRM." In many cases, the BFE on the FIRM is higher than the stillwater elevations shown in Table 17 due to the presence of wave effects. The higher elevation should be used for construction and/or floodplain management purposes.

## 2.5.4 Limit of Moderate Wave Action

Laboratory tests and field investigations have shown that wave heights as little as 1.5 feet can cause damage to and failure of typical Zone AE building construction. Wood-frame, light gage steel, or masonry walls on shallow footings or slabs are subject to damage when exposed to waves less than 3 feet in height. Other flood hazards associated with coastal waves (floating debris, high velocity flow, erosion, and scour) can also damage Zone AE construction.

Therefore, a LiMWA boundary may be shown on the FIRM as an informational layer to assist coastal communities in safe rebuilding practices. The LiMWA represents the approximate landward limit of the 1.5-foot breaking wave. The location of the

LiMWArelative to Zone VE and Zone AE is shown in Figure 6.

The effects of wave hazards in Zone AE between Zone VE (or the shoreline where Zone VE is not identified) and the limit of the LiMWA boundary are similar to, but less severe than, those in Zone VE where 3-foot or greater breaking waves are projected to occur during the 1% annual chance flooding event. Communities are therefore encouraged to adopt and enforce more stringent floodplain management requirements than the minimum NFIP requirements in the LiMWA. The NFIP Community Rating System provides credits for these actions.

Where wave runup elevations dominate over wave heights, there is no evidence to date of significant damage to residential structures by runup depths less than 3 feet. Examples of these areas include areas with steeply sloped beaches, bluffs, or flood protection structures that lie parallel to the shore. In these areas, the FIRM shows the LiMWA immediately landward of the VE/AE boundary. Similarly, in areas where the zone VE designation is based on the presence of a primary frontal dune or wave overtopping, the LiMWA is delineated immediately landward of the Zone VE/AE boundary.

## **SECTION 3.0 – INSURANCE APPLICATIONS**

### 3.1 National Flood Insurance Program Insurance Zones

For flood insurance applications, the FIRM designates flood insurance rate zones as described in Figure 3, "Map Legend for FIRM." Flood insurance zone designations are assigned to flooding sources based on the results of the hydraulic or coastal analyses. Insurance agents use the zones shown on the FIRM and depths and base flood elevations in this FIS Report in conjunction with information on structures and their contents to assign premium rates for flood insurance policies.

The 1% annual chance floodplain boundary corresponds to the boundary of the areas of special flood hazards (e.g. Zones A, AE, V, VE, etc.), and the 0.2% annual chance floodplain boundary corresponds to the boundary of areas of additional flood hazards.

Table 3 lists the flood insurance zones in the unincorporated and incorporated areas of the City and Borough of Juneau, Alaska.

Community	Flood Zone(s)
The City and Borough of Juneau	A, AE, AO, AH, V, VE, X

### 3.2 Coastal Barrier Resources System

This section is Not Applicable to this Flood Risk Project.

## Table 4: Coastal Barrier Resources System Information

[Not Applicable to this Flood Risk Project]

## **SECTION 4.0 – AREA STUDIED**

## 4.1 Basin Description

Table 5 contains a description of the characteristics of the HUC-8 sub-basins within which each community falls. The table includes the main flooding sources within each basin, a brief description of the basin, and its drainage area.

HUC-8 Sub- Basin Name	HUC-8 Sub-Basin Number	Primary Flooding Source	Description of Affected Area	Drainage Area (square miles)
Lynn Canal	19010301	Lynn Canal, Gastineau Channel	Sparsely-populated, remote and mountainous landscape with peaks rising to 4,000 and more, region has undergone severe glacial action, exaggerating steep mountain slopes and leaving U- shaped valleys through which larger rivers flow. Juneau and Douglas are only incorporated towns.	3,303
Taku River	19010304	Taku River	Sparsely-populated, remote and mountainous landscape.	N/A
Holkham Bay	19010206	Holkham Bay	Sparsely-populated, remote and mountainous landscape	N/A
Admiralty Island	19010204	Stephens Passage	Admiralty Island. Sparsely- populated, remote and mountainous landscape.	N/A
Icy Strait- Chatham Strait	19010500	Stephens Passage	Frederick Sound and Stephens Passage Open Water	N/A

## **Table 5: Basin Characteristics**

## 4.2 **Principal Flood Problems**

Table 6 contains a description of the principal flood problems that have been noted for the City and Borough of Juneau, Alaska by flooding source.

Flooding Source	Description of Flood Problems
All sources	Floods in the Juneau area can occur as a result of a combination of factors including heavy snowpack, temperature fluctuations, and precipitation. Since most development is along coastlines, most serious stream flooding will result when peak stream flows occur simultaneously with high tides. This causes streams to back up and flooding at higher elevations. High winds combined with high tides create storm surge and wave runup, representing the greatest flooding threat to the coastal areas.
	In addition to high tides and coastal storms, other flood problems are inadequate culverts and bridges which become blocked by debris and ice, developments that encroach onto and obstruct natural floodplains, high velocity flow, and siltation of culverts. Along some creeks, there are stockpiles of logs which increase flooding if carried downstream to a constriction.
Mendenhall River	Moderate flooding has occurred in the past in Mendenhall Valley, primarily resulting from flood flows on the smaller streams. Except for Montana Creek, the streams in the valley flow through fairly dense residential areas with numerous bridges and culverts which cause most of the flooding. Largest recorded floods occurred in 1927 and 1943 (USACE, 1970).
Lemon Creek	Along Lemon Creek is the Old Glacier Highway bridge, the only major constriction to this stream's flow. The most serious flooding of Lemon Creek occurs just above this bridge. Dredging of lower Lemon Creek ended in the mid-1980s and increased sedimentation within the channel will likely increase flooding risks in the vicinity.
Gold Creek	Flooding occurred Prior to channelization in 1958. No serious events since.
Coastal – Gastineau Channel & Fritz Cove	Coastal flooding influences occur on the downstream reaches of the Mendenhall River, Duck Creek, and Lemon Creek. One-percent chance flood of 23.4 feet occurs at the downstream end of each stream study reach.

## **Table 6: Principal Flood Problems**

Table 7 contains information about historic flood elevations in the communities within the City and Borough of Juneau, Alaska.

Flooding Source	Location	Historic Peak (Feet NAD83)	Event Date	Approximate Recurrence Interval (years)	Source of Data
Jordan Creek	USGS Gage	10.07	9/30/15	*	National Weather Service
Lemon Creek	USGS Gage	12.3	9/30/15	*	National Weather Service
Mendenhall River	All along river	*	1927 & 1943	*	Flood Insurance Study 8/19/2013

**Table 7: Historic Flooding Elevations** 

\* Data not Available

## 4.3 Non-Levee Flood Protection Measures

Table 8 contains information about non-levee flood protection measures within City and Borough of Juneau, Alaska such as dams, jetties, and or dikes. Levees are addressed in Section 4.4 of this FIS Report.

Flooding Source	Structure Name	Type of Measure	Location	Description of Measure
Gastinau Channel	Glacier Highway	Rock Revetments	Tidal area between Juneau and Juneau Airport	To provide protection against coastal storms and flooding
Gastinau Channel	Juneau International Airport	Dikes	Perimiter of property facing channel	To protect airport from coastal flooding

#### 4.4 Levees

This section is not applicable to this Flood Risk Project.

## Table 9: Levees

[Not Applicable to this Flood Risk Project]

## **SECTION 5.0 – ENGINEERING METHODS**

For the flooding sources in the community, standard hydrologic and hydraulic study methods were used to determine the flood hazard data required for this study. Flood events of a magnitude that are expected to be equaled or exceeded at least once on the average during any 10-, 25-, 50-, 100-, or 500-year period (recurrence interval) have been selected as having special significance for floodplain management and for flood insurance rates. These events, commonly termed the 10-, 25-, 50-, 100-, and 500-year floods, have a 10-, 4-, 2-, 1-, and 0.2% annual chance, respectively, of being equaled or exceeded during any year.

Although the recurrence interval represents the long-term, average period between floods of a specific magnitude, rare floods could occur at short intervals or even within the same year. The risk of experiencing a rare flood increases when periods greater than 1 year are considered. For example, the risk of having a flood that equals or exceeds the 100-year flood (1-percent chance of annual exceedance) during the term of a 30-year mortgage is approximately 26 percent (about 3 in 10); for any 90-year period, the risk increases to approximately 60 percent (6 in 10). The analyses reported herein reflect flooding potentials based on conditions existing in the community at the time of completion of this study. Maps and flood elevations will be amended periodically to reflect future changes.

In addition to these flood events, the "1-percent-plus", or "1%+", annual chance flood elevation has been modeled and included on the flood profile for certain flooding sources in this FIS Report. While not used for regulatory or insurance purposes, this flood event has been calculated to help illustrate the variability range that exists between the regulatory 1% annual chance flood elevation and a 1% annual chance elevation that has taken into account an additional amount of uncertainty in the flood discharges (thus, the 1% "plus"). For flooding sources whose discharges were estimated using regression equations, the 1%+ flood elevations are derived by taking the 1% annual chance flood discharges and increasing the modeled discharges by a percentage equal to the average predictive error for the regression equation. For flooding sources with gage- or rainfall-runoff-based discharge estimates, the upper 84-percent confidence limit of the discharges is used to compute the 1%+ flood elevations.

The engineering analyses described here incorporate the results of previously issued Letters of Map Change (LOMCs) listed in Table 27, "Incorporated Letters of Map Change", which include Letters of Map Revision (LOMRs). For more information about LOMRs, refer to Section 6.5, "FIRM Revisions."

### 5.1 Hydrologic Analyses

Hydrologic analyses were carried out to establish the peak elevation-frequency relationships for floods of the selected recurrence intervals for each flooding source studied. Hydrologic analyses are typically performed at the watershed level. Depending on factors such as watershed size and shape, land use and urbanization, and natural or man-made storage, various models or methodologies may be applied. A summary of the hydrologic methods applied to develop the discharges used in the hydraulic analyses for each stream is provided in Table 13. Greater detail (including assumptions, analysis, and results) is available in the archived project documentation.

A summary of the discharges is provided in Table 10. Frequency Discharge-Drainage Area Curves used to develop the hydrologic models may also be shown in Figure 7 for selected flooding sources. A summary of stillwater elevations developed for non-coastal flooding sources is provided in Table 11. (Coastal stillwater elevations are discussed in Section 5.3 and shown in Table 15.) Stream gage information is provided in Table 12.

The hydrologic analysis conducted by the USACE included a review of all existing floodfrequency data for the area and the utilization of analytical techniques best suited to the specific stream databases. All of the streams were evaluated on a regional frequency basis. However, the final analysis of each stream was made using an annual series frequency analysis, USGS and U.S. Department of Agriculture regression equations, and a model study using the Streamflow Synthesis and Reservoir Regulation (SSARR) computer program developed by the USACE (Reference 12). Statistical analyses were conducted in accordance with Water Resources Council guidelines for the determination of log-Pearson Type III frequency distributions (Reference 13). Model studies consisted of basin calibration based on historic information and the subsequent generation of peak floods as determined from the 10-, 2-, 1-, and 0.2-percent-annual-chance precipitation inputs obtained from the Weather Bureau (References 14 and 15). The maximum precipitation level was also obtained from the National Weather Service.

The SSARR model was developed initially without urbanization to ensure that the peak runoff values were consistent with other local unurbanized drainage basins. The basins were then broken down into subbasins which were consistent with culverts and other physical constraints. The relationships of storage versus elevation and discharge were developed for each control point. Discharge relationships were further influenced by tailwater encroachment from the downstream pondage. The total outflow volumes and subsequent area of inundation under this analysis remained similar to that of the analysis for uncontrolled conditions. The net change is a reduction in peak flow throughout the two basins.

During the summer months, runoff from Montana Creek is dependent on the amount of precipitation and not on the temperature. By contrast, the effect of higher temperatures on glacial melt is dramatic throughout the summer and masks the runoff due to precipitation in the Mendenhall River basin. About 90 percent of the runoff from the Mendenhall River occurs during the summer indicating that glacial melt accounts for a substantial amount of the total flow. However, the runoff characteristics of the Mendenhall River are not common to most of the streams in Juneau. Runoff patterns for the majority of the streams were found to be more closely related to those of Montana Creek.

The revised flood frequency analysis for the Mendenhall River was conducted using USGS gage data from both the Mendenhall River and Montana Creek (Reference 6). The USGS maintains a gage station at the upstream end of the Mendenhall River (Stat.15052500), and on Montana Creek (Stat.15052800) upstream of the confluence, with 34 and 17 years of peak-flow records, respectively. The 0.2-percent annual chance peak discharge for the Mendenhall River was obtained from a separate USGS report (Reference 16).

#### <u>Coastal</u>

Determination of tidal elevations used for the USACE's coastal study in the original FIS (Reference 8) was made by utilizing the local tide exceedance frequency combined with a wind exceedance frequency. Therefore, there is some overlap in the data provided. These data reflect a more conservative approach. Elevations were only determined for the 10- and 1-percent-annual-chance frequency floods. The tidal information was obtained from the National Oceanic and Atmospheric Administration (Reference 17). This information indicated that an extreme tide range of 28 feet was prevalent in the Juneau area and the maximum high tide varied from 22.0 feet in the area north of Juneau to 22.5 feet at Douglas Island. These elevations were modified slightly for sheltered areas that are protected from wave runup. These maximum tides are the highest recorded or the highest estimated tides which include meteorological effects and therefore have no determinable frequency.

# Table 10: Summary of Discharges (continued)

1 The Duck Creek watershed and associated tributaries are affected by urbanization. In addition, the unnamed tributary to Duck Creek and the East Fork of Duck Creek have drainage areas outside of the permissible range for use of Region 1 regression equations.

2 The Jordan Creek watershed gage peak-flow record is limited to 9 years.

3 The Lemon Creek watershed includes a portion of the Lemon Creek Glacier and therefore Lemon Creek may be subject to periodic release of glacial impoundments. \*Not calculated for this Flood Risk Project

#### 5.2 Hydraulic Analyses

Analyses of the hydraulic characteristics of flooding from the sources studied were carried out to provide estimates of the elevations of floods of the selected recurrence intervals. Base flood elevations on the FIRM represent the elevations shown on the Flood Profiles and in the Floodway Data tables in the FIS Report. Rounded whole-foot elevations may be shown on the FIRM in coastal areas, areas of ponding, and other areas with static base flood elevations. These whole-foot elevations may not exactly reflect the elevations derived from the hydraulic analyses. Flood elevations shown on the FIRM are primarily intended for flood insurance rating purposes. For construction and/or floodplain management purposes, users are cautioned to use the flood elevation data presented in this FIS Report in conjunction with the data shown on the FIRM. The hydraulic analyses for this FIS were based on unobstructed flow. The flood elevations shown on the profiles are thus considered valid only if hydraulic structures remain unobstructed, operate properly, and do not fail.

For streams for which hydraulic analyses were based on cross sections, locations of selected cross sections are shown on the Flood Profiles (Exhibit 1). For stream segments for which a floodway was computed (Section 6.3), selected cross sections are also listed on Table 24, "Floodway Data."

A summary of the methods used in hydraulic analyses performed for this project is provided in Table 13. Roughness coefficients are provided in Table 14. Roughness

coefficients are values representing the frictional resistance water experiences when passing overland or through a channel. They are used in the calculations to determine water surface elevations. Greater detail (including assumptions, analysis, and results) is available in the archived project documentation.

Detailed studies for the Eagle River, Eagle River By-Pass, Herbert River, Herbert River By-Pass, Tributary to Favorite Channel, Tributary to Favorite Channel By-Pass, Peterson Creek, Montana Creek, Montana Creek Overflow, and Salmon Creek, were conducted by the USACE as part of the original FIS study <sup>33</sup>. Detailed restudies of the Mendenhall River were initiated by the USGS, and finalized with analyses conducted by NHC (References 6,9,10,18.

The Alaska District of the USACE conducted field reconnaissance and surveys of key structures as part of the original FIS study. Bridges and culvert openings were field surveyed to obtain elevation data and structural geometry. Cross section data were developed from survey notes, field reconnaissance, photographs, and the use of the contour maps (References 19, 20, 21, and 22). For purposes of this study, the footbridge over the Herbert River and a private, decayed wooden bridge across Peterson Creek adjacent to the highway bridge were considered washed out and not restricting flow. All other bridges were considered to remain intact during flooding.

For the detailed restudies of the Mendenhall River the USGS conducted surveys to collect bridge, culvert, and cross-section geometry data. On the Mendenhall River, 57 cross-sections and two bridge structures were surveyed (Reference 9). On Lemon Creek, 40 cross-sections and two bridge structures were surveyed (Reference 6).

Water-surface profiles for detailed studies conducted by the USACE as part of the original FIS were computed with the USACE's HEC-2 step-backwater computer program (Reference 23). For the detailed restudies conducted by the USGS and NHC, water surface profiles were computed using the COE's HEC-RAS step-backwater computer program (Reference 24). Both programs compute the water-surface profile for stream channels at any cross section for either subcritical or supercritical flow conditions. The effects of various hydraulic structures such as bridges, culverts, weirs, and embankments are considered in the computation. This method applies Bernoulli's Theorem for the local energy at each cross sections, determined in terms of the average of the conveyances at the two ends of the reach.

The HEC-RAS models provided to NHC by the USGS did not include the entire effective detailed study reaches from the original FIS of the Mendenhall River (Reference 8). As a result, merging the effective studies with the newer models was required. On the upper 0.5 mile of the Mendenhall River, upstream of cross section AB, the original effective mapping and BFEs were adopted.

Starting water-surface elevations for Eagle River, Herbert River, Tributary to Favorite Channel, Peterson Creek, Mendenhall River, and Salmon Creek were based on a high tide that would occur during a month in which the 10-, 2-, 1-, or 0.2-percent-annual-chance floods were likely to occur. Starting water-surface elevations of the Eagle River By-Pass, the Herbert River By-Pass, Tributary to Favorite Channel By-Pass, and Montana Creek-

Overbank Flow were determined from the backwater computations of their respective main channels.

On Montana Creek, starting water-surface elevations were determined as those originally computed on the Mendenhall River at the confluence of the two reaches (Reference 8). Subsequently, results of the revised detailed study of the Mendenhall River yielded lower computed water-surface elevation than those reported in the original FIS. Despite this difference no adjustment was made to the starting water-surface elevations on Montana Creek because the reach was not restudied, thus the required computations to adjust the flood profiles and floodway data table could not be performed.

Flood profiles were drawn showing computed water-surface elevations to an accuracy of 0.5 foot for floods of the selected recurrence intervals. Locations of selected cross sections used in the hydraulic analyses are shown on the Flood Profiles (Exhibit 1).

A backwater study of Switzer Creek was performed starting at a water-surface elevation of 21 feet (Lemon Creek Backwater); but since the creek bed is low and does not rise appreciably until it leaves the study area, the rise in water-surface 2,000 feet upstream has increased only 0.23 foot at the 0.2-percent-annual-chance flood.

Coastal flooding influences also occur on the downstream reaches of the Mendenhall River and Duck Creek. A computed 1-percent-annual-chance coastal flood elevation of 23.4 feet occurs at the downstream end of each study reach.

The approximate study for the 1990 Effective streams was performed by running computed flood flows through cross sections determined by visual inspection and map and photographic interpretation. The Manning equation for open-channel flow was utilized in an iterative process to determine the depth of flow and to determine the area flooded. This method is explained in the Uniform Flow Equation method stated in the publication, Approximate Method for Quick Flood Plain Mapping <sup>27</sup>. The elevations were computed to known elevations obtained from historical information and high-water marks.

**Table 14: Roughness Coefficients** 

#### 5.3 Coastal Analyses

For the areas of City and Borough of Juneau that are impacted by coastal flooding processes, coastal flood hazard analyses were performed to provide estimates of coastal BFEs. Coastal BFEs reflect the increase in water levels during a flood event due to extreme tides and storm surge as well as overland wave effects.

The following subsections provide summaries of how each coastal process was considered for this FIS Report. Greater detail (including assumptions, analysis, and results) is available in the archived project documentation. Table 15 summarizes the methods and/or models used for the coastal analyses. Refer to Section 2.5.1 for descriptions of the terms used in this section.

# Table 15: Summary of Coastal Analyses

## 5.3.1 Total Stillwater Elevations

The total stillwater elevations (stillwater including storm surge plus wave setup) for the 1% annual chance flood were determined for areas subject to coastal flooding. The models and methods that were used to determine storm surge and wave setup are listed in Table 15. The stillwater elevation that was used for each transect in coastal analyses is shown in Table 17, "Coastal Transect Parameters." Figure 8 shows the total stillwater elevations for the 1% annual chance flood that was determined for this coastal analysis.

### Figure 8: 1% Annual Chance Total Stillwater Elevations for Coastal Areas

[Not Applicable to this Flood Risk Project]

#### Astronomical Tide

Astronomical tidal statistics were generated directly from local tidal constituents by sampling the predicted tide at random times throughout the tidal epoch.

#### Storm Surge Statistics

Storm surge is modeled based on characteristics of actual storms responsible for significant coastal flooding. The characteristics of these storms are typically determined by statistical study of the regional historical record of storms or by statistical study of tidal gages.

When historic records are used to calculate storm surge, characteristics such as the strength, size, track, etc., of storms are identified by site.

Tidal gages can be used instead of historic records of storms when the available tidal gage record for the area represents both the astronomical tide component and the storm surge component. Table 16 provides the gage name, managing agency, gage type, gage identifier, start date, end date, and statistical methodology applied to each gage used to determine the stillwater elevations.

## Table 16: Tide Gage Analysis Specifics

[Not Applicable to this Flood Risk Project]

**Combined Riverine and Tidal Effects** 

Riverine and surge rates for the lower reaches of the Mendenhall River were combined by developing curves for rate of occurrence vs. flood level for each flood source.

#### Wave Setup Analysis

Wave setup was computed during the storm surge modeling through the methods and models listed in Table 15 and included in the frequency analysis for the determination of the total stillwater elevations.

## 5.3.2 Waves

The detailed coastal study performed by the USACE as part of the original FIS relied on methodologies outlined in the USACE's Shore Protection Manual for their analysis (Reference 29). A detailed study was performed in Favorite Channel at Point Lena, Lena Cove, and Eagle Harbor. Each location was analyzed for possible approaches of stormdriven waves. The fetch and wind speed for the most critical directions were then determined. With the aid of the fetch and wind speed, the manual provided the significant deepwater wave height, period, and length. To determine the depth classification, the average depth in the fetch was divided by the wave length. The transitional water was found in all cases. Therefore, the transitional water equations from the manual were used. The transitional water wave height, period, and length were then calculated and adjusted to account for refraction and shoaling. Refraction was negligible in most cases due to the steep beach slopes. Only Lena Cove and Eagle Harbor had measurable refraction, but other conditions made this refraction insignificant.

The manual produced the shoaling coefficient which allowed the calculating of the maximum deepwater wave height. With this and Figures 2-65 and 2-66 of the Shore Protection Manual, the breaking height and the breaking depth were determined. Figures 7-10 and 7-13 then provided the runup for each beach slope at each location.

Wave setup was calculated from equation 3-49 and wind setup from equation 3-83. These two values provided the storm surge component. The actual runup elevations were finally determined by adding storm surge and runup values to the tide level from the combined wind and tide frequency curve developed by the study contractor. Various tide elevations and wind speeds were tried to determine the highest possible 1-percent-annual-chance water-surface level. Wind setup was never greater than 0.2 foot due to the relatively short fetches and low wind speeds. The highest wave setup, 1.5 feet, occurred at Lena Cove. The underwater and above-water beach slopes were determined by available mapping, as well as by visual inspection.

## 5.3.3 Coastal Erosion

A single storm episode can cause extensive erosion in coastal areas. Storm-induced erosion was evaluated to determine the modification to existing topography that is expected to be associated with flooding events. Erosion was evaluated using the methods listed in Table 15.

#### 5.3.4 Wave Hazard Analyses

Overland wave hazards were evaluated to determine the combined effects of ground elevation, vegetation, and physical features on overland wave propagation and wave runup. These analyses were performed at representative transects along all shorelines for which waves were expected to be present during the floods of the selected recurrence intervals. The results of these analyses were used to determine elevations for the 1% annual chance flood.

Transect locations were chosen with consideration given to the physical land characteristics as well as development type and density so that they would closely represent conditions in their locality. Additional consideration was given to changes in the

total stillwater elevation. Transects were spaced close together in areas of complex topography and dense development or where total stillwater elevations varied. In areas having more uniform characteristics, transects were spaced at larger intervals. Transects shown in Figure 9, "Transect Location Map," Table17 provides the location, stillwater elevations, and starting wave conditions for each transect evaluated for overland wave hazards. In this table, "starting" indicates the parameter value at the beginning of the transect.

#### Wave Height Analysis

Wave height analyses were performed to determine wave heights and corresponding wave crest elevations for the areas inundated by coastal flooding and subject to overland wave propagation hazards. Refer to Figure 6 for a schematic of a coastal transect evaluated for overland wave propagationErr hazards.

Wave heights and wave crest elevations were modeled using the methods and models listed in Table 15, "Summary of Coastal Analyses".

#### Wave Runup Analysis

Wave runup analyses were performed to determine the height and extent of runup beyond the limit of stillwater inundation for the 1% annual chance flood. Wave runup elevations were modeled using the methods and models listed in Table 15.

The tidal data from Juneau and the wind data from Juneau and the Five Fingers Light Station (Reference 17) were used in the original analysis to derive tide exceedance frequency curves and combined wind and tide frequencies for the 10-, 2-, 1-, and 0.2-percent-annual-chance events for Point Lena, Lena Cove, and Eagle Harbor (southeasterly winds). Because the winds are relatively light and there is significant tidal influence, the higher tides combined with lighter winds caused the highest runups. This combined frequency method has been determined to be more reasonable than applying a certain year wind to a fixed level.

Flood levels observed by local residents, as well as high-water marks, compared favorably with calculated flood levels. In determining the actual storm surge and wave runup elevation, allowances were made for the irregular coastline. Refraction, beach slope, and the materials making up the shore and beach were considered. It is impossible to determine the frequency associated with the highest recorded tide, which included storm surge, but it is assumed to approximate the 1-percent-annual-chance event since it does not vary significantly from the computed 1-percent-annual-chance storm surge and wave runup.

The coastal areas specified for approximate study were compared to the areas in the detailed study, and approximate elevations for storm surge and wave runup were derived. Between the coastal high-hazard zone and the riverine zones, an approximate study is shown to tie these areas together. The water-surface plotted for this approximate study is the result of tidal flooding from a 1-percent-annual-chance tide. A smooth transition is made from the exposed beach with high runup to the sheltered areas blocked from runup but subject to storm surge.

NHC performed a detailed restudy of the shoreline along Gastineau Channel, Fritz Cove,

and Auke Bay that consisted of offshore wave modeling, nearshore hydraulic analysis, and coastal floodplain mapping (Reference 30). The purpose of this study was to apply FEMA's adopted Guidelines for Coastal Flood Hazard Analysis and Mapping for the Pacific Coast of the United States (Pacific Coast Guidelines) to analyze and map coastal hazards (Reference 31).

The Pacific Coast Guidelines provide recommended methods for analyzing the 1-percent annual-chance conditions for mapping. For open coast and sheltered waters along the Pacific Coast, the recommended approach is to simulate conditions for a series of historical events and then conduct statistical analyses on the resultant flood hazard data. This method, termed the Response-Based Method, typically involves modeling 10 to 20 large water level and wind events per year for a minimum of 30 years. Runup, overtopping, total water levels, and other hazard parameters are then calculated for each of these events. The annual maxima are then extracted for each year and fit with the Generalized Extreme Value distribution, typically using maximum likelihood or L-moments. One-percent-chance (i.e. 100-year) values are then calculated from the frequency analysis.

Computations progress from the offshore zone landward to the backshore zone, where they are used to define hazard zones. These zones provide a simple framework for wave and water-level analysis. The two-dimensional numerical model SWAN (Simulating Waves Nearshore) was used to simulate waves and water levels offshore, including shoaling effects. SWAN is a numerical model which simulates the growth, dissipation, and propagation of wind waves in coastal and inland waters. The model is available as free software under the terms of the GNU General Public License from the Technical University Delft or as a commercial version from Delft Hydraulics. The SWAN model is well documented and is widely used for wave predictions (Reference 32). To simplify the computation process, Gastineau Channel was modeled separately from Auke Bay and Fritz Cove.

The SWAN model requires three main types of input: 1) topographic and bathymetric elevations, 2) water levels, and 3) winds. In Juneau, elevation data used to develop the elevation grids came from multiple sources. The municipality provided bare-earth LiDAR topography as well as bathymetry from the National Oceanic and Atmospheric Association (NOAA) (Reference 23). Areas beyond the LiDAR coverage were supplemented with topography data from the Shuttle Radar Topography Mission (SRTM) (Reference 31). For this study, measured water level data were retrieved from NOAA Station 9452210. Hourly measurements were obtained from 1970 to 1979, and half-hourly measurements were obtained from 1980 to 2005.

The times of the occurrence of high tide (and low tide) are nearly uniform throughout the region. Also, the magnitudes of the tides are quite similar; therefore, no spatial corrections were used to adjust the measured tide data for the phase or amplitude in the Gastineau or Auke Bay/Fritz Cove domains. Hourly wind data from 1948 to 2008 were collected from the NOAA station at the Juneau Municipal Airport and a second, much shorter record (1998 to 2004), was obtained for Mayflower Island in Gastineau Channel. To understand the spatial variation in wind direction, frequency analyses of wind direction were performed at both the Juneau and Mayflower Island gages.

As mentioned previously, the Pacific Coast Guidelines recommend selecting the largest 10 to 20 events of each year for analysis for a minimum of 30 years. For this project, the 10 highest tides and 10 highest winds were selected for each year between 1970 and 2005 (35years). For any given year, some of the 10 highest wind events coincided with 10 highest tide events, so ultimately there were 10 to 20 storms selected for each year. With runs defined for each storm, the tide data and the wind data were paired together with the domain grid for analysis. SWAN results for each simulated event were then saved at select computational points, called pass points.

Each of these pass points corresponds to a unique transect that defines the cross-shore geometry and physical characteristics of the shoreline at a specific location. To represent the varied coastline, over 900 pass points and cross-shore transects spaced approximately every 328 feet (100 meters), were defined along the shoreline of Gastineau Channel and Auke Bay/Fritz Cove. Transects were positioned perpendicular to the shoreline and generally extended from the pass point to an elevation well above the predicted flood extents. Each transect was visually inspected to determine the location of the shore crest. The crest divides the transect into two general regions: the foreshore and the backshore. Each transect was cut from the same bathymetric/topographic surface used for the SWAN model using HEC-GeoRAS.

The nearshore hydraulic analysis was conducted using the equations and methods outlined in the Pacific Coast Guidelines. Wave runup and overtopping were calculated at every time step, for every event, at each transect. To expedite this analysis, a FORTRAN program named RUNUP was developed by NHC to read in data from SWAN, calculate runup and overtopping at each transect, and output the annual maxima for later use in frequency analyses. The shape of the transect profile determine which equations RUNUP uses to compute runup and overtopping. In order to assign roughness and runup values to the transects, a site investigation was performed to observe the study area from a boat. This investigation utilized a video camera and GPS equipment to create a georeferenced video of the shoreline. This video along with aerial photography and field notes was used to define the remaining physical features at each transect.

The annual maximums from the RUNUP analysis were then extracted for each transect and used to perform a frequency analysis. Following the recommended approach outlined in the Pacific Coast Guidelines, the annual maximums at each transect were fit to a generalized extreme value (GEV) distribution using the method of maximum likelihood. The frequency analysis of the computed total water levels was used to determine the 10-, 2-, 1-, and 0.2-percent annual chance flood events. These elevations were reviewed to ensure that the results were reasonable based on observed historical flood data.

Coastal flood hazard areas with water depths less than 3 feet or runup less than 2 feet were classified as AE Zones because they were not considered high velocity impact zones.

# **SECTION 6.0 – MAPPING METHODS**

### 6.1 Vertical and Horizontal Control

All FIS Reports and FIRMs are referenced to a specific vertical datum. The vertical datum provides a starting point against which flood, ground, and structure elevations can be referenced and compared. Because the City and Borough of Juneau is a coastal community that has historically referenced elevations to a tidal datum, all flood elevations shown in this FIS report and on the DFIRM are referenced to the Mean Lower Low Water (MLLW) vertical datum at station 9454050 for the Modified Procedure for Tidal Datum Calculation Epoch of 2002 to 2006 (MPTDC epoch 2002-2006).

The shoreline displayed on the maps is based on a MHW elevation of 15.3 feet (MLLW).

For information, visit the National Geodetic Survey website at www.ngs.noaa.gov, or contact the National Geodetic Survey at the following address:

NGS Information Services NOAA, N/NGS12 National Geodetic Survey SSMC-3, #9202 1315 East-West Highway Silver Spring, Maryland 20910-3282 (301) 713-3242

Temporary vertical monuments are often established during the preparation of a flood hazard analysis for the purpose of establishing local vertical control. Although these monuments are not shown on the FIRM, they may be found in the archived project documentation associated with the FIS Report and the FIRMs for this community. Interested individuals may contact FEMA to access these data.

To obtain current elevation, description, and/or location information for benchmarks in the area, please contact information services Branch of the NGS at (301) 713-3242, or visit their website at www.ngs.noaa.gov.

The datum conversion locations and values that were calculated for the City and Borough of Juneau, Alaska are provided in Table 20.

## Table 20: Countywide Vertical Datum Conversion

[Not Applicable to this Flood Risk Project]

A countywide conversion factor could not be generated for the City and Borough of Juneau, Alaska because the maximum variance from average exceeds 0.25 feet. Calculations for the vertical offsets on a stream by stream basis are depicted in Table 21.

#### Table 21: Stream-Based Vertical Datum Conversion

[Not Applicable to this Flood Risk Project]

#### 6.2 Base Map

The FIRMs and FIS Report for this project have been produced in a digital format. The flood hazard information was converted to a Geographic Information System (GIS) format that meets FEMA's FIRM Database specifications and geographic information standards. This information is provided in a digital format so that it can be incorporated into a local GIS and be accessed more easily by the community. The FIRM Database includes most of the tabular information contained in the FIS Report in such a way that the data can be associated with pertinent spatial features. For example, the information contained in the Floodway Data table and Flood Profiles can be linked to the cross sections that are shown on the FIRMs.

Additional information about the FIRM Database and its contents can be found in FEMA's *Guidelines and Standards for Flood Risk Analysis and Mapping*, www.fema.gov/guidelines-and-standards-flood-risk-analysis-and-mapping.

Base map information shown on the FIRM was derived from the sources described in Table 22.

### 6.3 Floodplain and Floodway Delineation

The FIRM shows tints, screens, and symbols to indicate floodplains and floodways as well as the locations of selected cross sections used in the hydraulic analyses and floodway computations.

For riverine flooding sources, the mapped floodplain boundaries shown on the FIRM have been delineated using the flood elevations determined at each cross section; between cross sections, the boundaries were interpolated using the topographic elevation data described in Table 23. For each coastal flooding source studied as part of this FIS Report, the mapped floodplain boundaries on the FIRM have been delineated using the flood and wave elevations determined at each transect; between transects, boundaries were delineated using land use and land cover data, the topographic elevation data described in Table 23, and knowledge of coastal flood processes. In ponding areas, flood elevations were determined at each junction of the model; between junctions, boundaries were interpolated using the topographic elevation data described in Table 23.

In cases where the 1% and 0.2% annual chance floodplain boundaries are close together, only the 1% annual chance floodplain boundary has been shown. Small areas within the floodplain boundaries may lie above the flood elevations but cannot be shown due to limitations of the map scale and/or lack of detailed topographic data.

The floodway widths presented in this FIS Report and on the FIRM were computed for certain stream segments on the basis of equal conveyance reduction from each side of the floodplain. Floodway widths were computed at cross sections. Between cross sections, the floodway boundaries were interpolated. Table 2 indicates the flooding sources for which floodways have been determined. The results of the floodway computations for those flooding sources have been tabulated for selected cross sections and are shown in Table 24, "Floodway Data."

# Table 25: Flood Hazard and Non-Encroachment Data for Selected Streams

[Not Applicable to this Flood Risk Project]

# 6.4 Coastal Flood Hazard Mapping

Flood insurance zones and BFEs including the wave effects were identified on each transect based on the results from the onshore wave hazard analyses. Between transects, elevations were interpolated using topographic maps, land-use and land-cover data, and knowledge of coastal flood processes to determine the aerial extent of flooding. Sources for topographic data are shown in Table 23.

Zone VE is subdivided into elevation zones and BFEs are provided on the FIRM.

The limit of Zone VE shown on the FIRM is defined as the farthest inland extent of any of these criteria (determined for the 1% annual chance flood condition):

- The *primary frontal dune zone* is defined in 44 CFR Section 59.1 of the NFIP regulations. The primary frontal dune represents a continuous or nearly continuous mound or ridge of sand with relatively steep seaward and landward slopes that occur immediately landward and adjacent to the beach. The primary frontal dune zone is subject to erosion and overtopping from high tides and waves during major coastal storms. The inland limit of the primary frontal dune zone occurs at the point where there is a distinct change from a relatively steep slope to a relatively mild slope.
- The *wave runup zone* occurs where the (eroded) ground profile is 3.0 feet or more below the 2-percent wave runup elevation.
- The *wave overtopping splash zone* is the area landward of the crest of an overtopped barrier, in cases where the potential 2-percent wave runup exceeds the barrier crest elevation by 3.0 feet or more.
- The *breaking wave height zone* occurs where 3-foot or greater wave heights could occur (this is the area where the wave crest profile is 2.1 feet or more above the total stillwater elevation).
- The *high-velocity flow zone* is landward of the overtopping splash zone (or area on a sloping beach or other shore type), where the product of depth of flow times the flow velocity squared (hv<sup>2</sup>) is greater than or equal to 200 ft<sup>3</sup>/sec<sup>2</sup>. This zone may only be used on the Pacific Coast.

The SFHA boundary indicates the limit of SFHAs shown on the FIRM as either "V" zones or "A" zones.

Table 26 indicates the coastal analyses used for floodplain mapping and the criteria used to determine the inland limit of the open-coast Zone VE and the SFHA boundary at each transect.

## Table 26: Summary of Coastal Transect Mapping Considerations

[Not Applicable to this Flood Risk Project]

#### 6.5 **FIRM Revisions**

This FIS Report and the FIRM are based on the most up-to-date information available to FEMA at the time of its publication; however, flood hazard conditions change over time. Communities or private parties may request flood map revisions at any time. Certain types of requests require submission of supporting data. FEMA may also initiate a revision. Revisions may take several forms, including Letters of Map Amendment (LOMAs), Letters of Map Revision Based on Fill (LOMR-Fs), Letters of Map Revision (LOMRs) (referred to collectively as Letters of Map Change (LOMCs)), Physical Map Revisions (PMRs), and FEMA-contracted restudies. These types of revisions are further described below. Some of these types of revisions do not result in the republishing of the FIS Report. To assure that any user is aware of all revisions, it is advisable to contact the community repository of flood-hazard data (shown in Table 31, "Map Repositories").

### 6.5.1 Letters of Map Amendment

A LOMA is an official revision by letter to an effective NFIP map. A LOMA results from an administrative process that involves the review of scientific or technical data submitted by the owner or lessee of property who believes the property has incorrectly been included in a designated SFHA. A LOMA amends the currently effective FEMA map and establishes that a specific property is not located in a SFHA. A LOMA cannot be issued for properties located on the PFD (primary frontal dune).

To obtain an application for a LOMA, visit http://www.fema.gov and download the form "MT-1 Application Forms and Instructions for Conditional and Final Letters of Map Amendment and Letters of Map Revision Based on Fill". Visit the "Flood Map-Related Fees" section to determine the cost, if any, of applying for a LOMA.

FEMA offers a tutorial on how to apply for a LOMA. The LOMA Tutorial Series can be accessed at http://www.fema.gov/plan/prevent/fhm/ot\_Imreq.shtm.

For more information about how to apply for a LOMA, call the FEMA Map Information eXchange; toll free, at 1-877-FEMA MAP (1-877-336-2627).

### 6.5.2 Letters of Map Revision Based on Fill

A LOMR-F is an official revision by letter to an effective NFIP map. A LOMR-F states FEMA's determination concerning whether a structure or parcel has been elevated on fill above the base flood elevation and is, therefore, excluded from the SFHA.

Information about obtaining an application for a LOMR-F can be obtained in the same manner as that for a LOMA, by visiting http://www.fema.gov for the "MT-1 Application Forms and Instructions for Conditional and Final Letters of Map Amendment and Letters of Map Revision Based on Fill" or by calling the FEMA Map Information eXchange, toll free, at 1-877-FEMA MAP (1-877-336-2627). Fees for applying for a LOMR-F, if any, are listed in the "Flood Map-Related Fees" section.

A tutorial for LOMR-F is available at http://www.fema.gov/plan/prevent/fhm/ot\_Imreq.shtm.

# 6.5.3 Letters of Map Revision

A LOMR is an official revision to the currently effective FEMA map. It is used to change flood zones, floodplain and floodway delineations, flood elevations and planimetric features. All requests for LOMRs should be made to FEMA through the chief executive officer of the community, since it is the community that must adopt any changes and revisions to the map. If the request for a LOMR is not submitted through the chief executive officer of the community, evidence must be submitted that the community has been notified of the request.

To obtain an application for a LOMR, visit http://www.fema.gov and download the form "MT-2 Application Forms and Instructions for Conditional Letters of Map Revision and Letters of Map Revision". Visit the "Flood Map-Related Fees" section to determine the cost of applying for a LOMR. For more information about how to apply for a LOMR, call the FEMA Map Information eXchange; toll free, at 1-877-FEMA MAP (1-877-336-2627) to speak to a Map Specialist.

Previously issued mappable LOMCs (including LOMRs) that have been incorporated into the City and Borough of Juneau, Alaska FIRM are listed in Table 27. Please note that this table only includes LOMCs that have been issued on the FIRM panels updated by this map revision. For all other areas within this county, users should be aware that revisions to the FIS Report made by prior LOMRs may not be reflected herein and users will need to continue to use the previously issued LOMRs to obtain the most current data.

# Table 27: Incorporated Letters of Map Change

[Not Applicable to this Flood Risk Project]

# 6.5.4 Physical Map Revisions

Physical Map Revisions (PMRs) are an official republication of a community's NFIP map to effect changes to base flood elevations, floodplain boundary delineations, regulatory floodways and planimetric features. These changes typically occur as a result of structural works or improvements, annexations resulting in additional flood hazard areas or correction to base flood elevations or SFHAs.

The community's chief executive officer must submit scientific and technical data to FEMA to support the request for a PMR. The data will be analyzed and the map will be revised if warranted. The community is provided with copies of the revised information and is afforded a review period. When the base flood elevations are changed, a 90-day appeal period is provided. A 6-month adoption period for formal approval of the revised map(s) is also provided.

For more information about the PMR process, please visit http://www.fema.gov and visit the "Flood Map Revision Processes" section.

### 6.5.5 Contracted Restudies

The NFIP provides for a periodic review and restudy of flood hazards within a given community. FEMA accomplishes this through a national watershed-based mapping needs assessment strategy, known as the Coordinated Needs Management Strategy (CNMS). The CNMS is used by FEMA to assign priorities and allocate funding for new flood hazard

analyses used to update the FIS Report and FIRM. The goal of CNMS is to define the validity of the engineering study data within a mapped inventory. The CNMS is used to track the assessment process, document engineering gaps and their resolution, and aid in prioritization for using flood risk as a key factor for areas identified for flood map updates. Visit www.fema.gov to learn more about the CNMS or contact the FEMA Regional Office listed in Section 8 of this FIS Report.

# 6.5.6 Community Map History

The current FIRM presents flooding information for the entire geographic area of the City and Borough of Juneau, Alaska. Previously, separate FIRMs, Flood Hazard Boundary Maps (FHBMs) and/or Flood Boundary and Floodway Maps (FBFMs) may have been prepared for the incorporated communities and the unincorporated areas in the county that had identified SFHAs. Current and historical data relating to the maps prepared for the project area are presented in Table 28, "Community Map History." A description of each of the column headings and the source of the date is also listed below.

- Community Name includes communities falling within the geographic area shown on the FIRM, including those that fall on the boundary line, nonparticipating communities, and communities with maps that have been rescinded. Communities with No Special Flood Hazards are indicated by a footnote. If all maps (FHBM, FBFM, and FIRM) were rescinded for a community, it is not listed in this table unless SFHAs have been identified in this community.
- Initial Identification Date (First NFIP Map Published) is the date of the first NFIP map that identified flood hazards in the community. If the FHBM has been converted to a FIRM, the initial FHBM date is shown. If the community has never been mapped, the upcoming effective date or "pending" (for Preliminary FIS Reports) is shown. If the community is listed in Table 28 but not identified on the map, the community is treated as if it were unmapped.
- *Initial FHBM Effective Date* is the effective date of the first Flood Hazard Boundary Map (FHBM). This date may be the same date as the Initial NFIP Map Date.
- *FHBM Revision Date(s)* is the date(s) that the FHBM was revised, if applicable.
- *Initial FIRM Effective Date* is the date of the first effective FIRM for the community. This is the first effective date that is shown on the FIRM panel.
- FIRM Revision Date(s) is the date(s) the FIRM was revised, if applicable. This is
  the revised date that is shown on the FIRM panel, if applicable. As countywide
  studies are completed or revised, each community listed should have its FIRM
  dates updated accordingly to reflect the date of the countywide study. Once the
  FIRMs exist in countywide format, as Physical Map Revisions (PMR) of FIRM
  panels within the county are completed, the FIRM Revision Dates in the table for
  each community affected by the PMR are updated with the date of the PMR, even
  if the PMR did not revise all the panels within that community.

The initial effective date for the City and Borough of Juneau, Alaska FIRMs in countywide format was February 4, 1981.

# Table 28: Community Map History

Community Name	Initial Identification Date (First NFIP Map Published)	Initial FHBM Effective Date	FHBM Revision Date(s)	Initial FIRM Effective Date	FIRM Revision Date(s)
City and Borough of Juneau, Alaska	05/09/70	N/A	05/20/77	02/04/81	09/28/90 08/19/13

# SECTION 7.0 – CONTRACTED STUDIES AND COMMUNITY COORDINATION

# 7.1 Contracted Studies

Table 29 provides a summary of the contracted studies, by flooding source, that are included in this FIS Report.

Flooding Source	FIS Report Dated	Contractor	Number	Work Completed Date	Affected Communities
All within HUC 19010301	March, 1977	Alaska District, US Army COE	IAA-H-7-76	March 1977	City and Borough of Juneau, AK
Montana Creek	September 28, 1990	Alaska District, US Army COE	EMW-87-E- 2509	September 28, 1990	City and Borough of Juneau, AK
Mendenhall River	September 28, 1990	Alaska District, US Army COE	EMW-87-E- 2509	September 28, 1990	City and Borough of Juneau, AK
Mendenhall River	August 19, 2013	Northwest Hydraulic Consultants	EMS-2001- C0-0067	2010	City and Borough of Juneau, AK
Auke Bay	August 19, 2013	Northwest Hydraulic Consultants	EMS-2001- C0-0067	2010	City and Borough of Juneau, AK
Fritz Cove	August 19, 2013	Northwest Hydraulic Consultants	EMS-2001- C0-0067	2010	City and Borough of Juneau, AK
Gastineau Channel	August 19, 2013	Northwest Hydraulic Consultants	EMS-2001- C0-0067	2010	City and Borough of Juneau, AK
Lemon Creek	September 18, 2020	STARR	HSFEHQ-09- D-370	1/21/2016	City and Borough of Juneau, AK

Flooding Source	FIS Report Dated	Contractor	Number	Work Completed Date	Affected Communities
Duck Creek	September 18, 2020	STARR	HSFEHQ-09- D-370	1/21/2016	City and Borough of Juneau, AK
East Fork Duck Creek	September 18, 2020	STARR	HSFEHQ-09- D-370	1/21/2016	City and Borough of Juneau, AK
Jordan Creek	September 18, 2020	STARR	HSFEHQ-09- D-370	1/21/2016	City and Borough of Juneau, AK
Unammed Tributary to Duck Creek	September 18, 2020	STARR	HSFEHQ-09- D-370	1/21/2016	City and Borough of Juneau, AK
Gold Creek, Auke Lake	September 18, 2020	STARR	HSFEHQ-09- D-370	1/21/2016	City and Borough of Juneau, AK

# 7.2 Community Meetings

The dates of the community meetings held for this Flood Risk Project and any previous Flood Risk Projects are shown in Table 30. These meetings may have previously been referred to by a variety of names (Community Coordination Officer (CCO), Scoping, Discovery, etc.), but all meetings represent opportunities for FEMA, community officials, study contractors, and other invited guests to discuss the planning for and results of the project.

Community	FIS Report Dated	Date of Meeting	Meeting Type	Attended By	
City and Borough of	08/04/80	07/21/77 CCO Initial		FEMA, City and Borough of Juneau, Study Contractor	
Juneau, Alaska	08/04/80	08/22/77	CCO Final	FEMA, City and Borough of Juneau, Study Contractor	
City and Borough of Juneau, Alaska	09/28/90	N/A	N/A	N/A	
City and Borough of	09/10/12	04/27/05	CCO Initial	FEMA, USGS, State of Alaska, City and Borough of Juneau, Study Contractor	
Juneau, Alaska	08/19/13	12/02/10	CCO Final	FEMA, City and Borough of Juneau, Study Contractor, Developers, Public	

# **SECTION 8.0 – ADDITIONAL INFORMATION**

Information concerning the pertinent data used in the preparation of this FIS Report can be obtained by submitting an order with any required payment to the FEMA Engineering Library. For more information on this process, see http://www.fema.gov.

In May 1969, the Army Corps of Engineers prepared a Special Flood Hazard Report on Salmon Creek (Reference 5). In June 1970, they conducted Flood Plain Information reports on the Mendenhall River and Lemon Creek (References 3 and 4). Flood Insurance Studies for the Mendenhall River and Lemon Creek were prepared in 1971 (References 36 and 37). A Flood Hazard Boundary Map for the City and Borough of Juneau was published on May 20, 1977 (Reference 38).

Table 31 is a list of the locations where FIRMs for the City and Borough of Juneau, Alaska can be viewed. Please note that the maps at these locations are for reference only and are not for distribution. Also, please note that only the maps for the community listed in the table are available at that particular repository. A user may need to visit another repository to view maps from an adjacent community.

#### Table 31: Map Repositories

Community	Address	City	State	Zip Code
City and Borough of Juneau, Alaska	Marine View Building 230 South Franklin Street	Juneau	AK	99801

The National Flood Hazard Layer (NFHL) dataset is a compilation of effective FIRM databases and LOMCs. Together they create a GIS data layer for a State or Territory. The NFHL is updated as studies become effective and extracts are made available to the public monthly. NFHL data can be viewed or ordered from the website shown in Table 32.

Table 32 contains useful contact information regarding the FIS Report, the FIRM, and other relevant flood hazard and GIS data. In addition, information about the state NFIP Coordinator and GIS Coordinator is shown in this table. At the request of FEMA, each Governor has designated an agency of State or territorial government to coordinate that State's or territory's NFIP activities. These agencies often assist communities in developing and adopting necessary floodplain management measures. State GIS Coordinators are knowledgeable about the availability and location of state and local GIS data in their state.
